Seed and Plant Improvement Research Department, Tehran Agricultural and Natural Resources Research and Education Center, AREEO, Varamin, Iran

Abstract: Two-year field experiments were conducted to investigate the effect of different tillage methods on soil physical properties and crop yield of melon. Tillage treatments in the study were moldboard plow + two passes of disk harrow as conventional tillage (CT), two passes of disk harrow as reduced tillage (RT), one pass of disk harrow as minimum tillage (MT) and no-tillage (NT) as direct drilling method. The statistical results of the study indicated that tillage method significantly (P≤0.05) affected crop yield, fruit weight, fruit length, fruit diameter, total soluble solids and root dry matter, but there was no significant differences in other components such as number of plants per hectare, number of fruits per plant and root length. The maximum value of crop yield (27.2 t ha⁻¹), number of plants per hectare (6360) and number of fruits per plant (1.9) was obtained in case of CT treatment, while maximum value of fruit weight (3.6 kg), total soluble solids (10.25%), root length (42.3 cm) and root dry matter (72.5%) was observed in case of RT treatment. Also, maximum value of fruit length (29.0 cm) and fruit diameter (17.2 cm) was noted in case of MT treatment. Conversely, the minimum value of crop yield (20.6 t ha⁻¹), number of plants per hectare (5910), fruit weight (1.9 kg), fruit length (26.4 cm), fruit diameter (14.1 cm), root length (36.6 cm) and root dry matter (54.1%) was obtained in case of NT treatment, while minimum value of number of fruits per plant (1.2) was observed in case of RT treatment. Moreover, minimum value of total soluble solids (9.75%) was noted in case of MT treatment. The statistical results of the study also indicated that tillage method significantly affected soil physical properties. The soil of the CT treatment had consistently the highest moisture contents (19.6%) and the lowest bulk density (1.41 g) and penetration resistance (560 kPa); while the soil of the NT treatment had the lowest moisture contents (16.8%) and the highest bulk density (1.52 g) and penetration resistance (1250 kPa). Therefore, moldboard plow followed by two passes of disk harrow was found to be more appropriate and profitable tillage method in improving soil physical properties and crop yield of melon due to reduced soil compaction, increased soil moisture content, enhanced seed-soil contact and suppressing weed growth.

Key words: Tillage methods - Soil physical properties - Crop yield - Melon - Iran

INTRODUCTION

Melon (Cucumis melo) is one of the most important vegetable crops of Iran and is well adapted to its soil and climatic condition. Melon ranks third in cultivated area and production after tomato and watermelon. The average production of melon has been 1.5 million tones during the last two years (Iranian Ministry of Agriculture, Statistical Yearbook, 2005). Although the use of improved varieties and fertilizers has increased melon production to much extent, the full potential of crop production has not yet been achieved.

Soil tillage is among the important factors affecting soil physical properties and crop yield. Among the crop production factors, tillage contributes up to 20% [1]. Tillage method affects the sustainable use of soil
resources through its influence on soil properties [2].

The proper use of tillage can improve soil related
constrains, while improper tillage may cause a range of
undesirable processes, e.g. destruction of soil structure,
accelerated erosion, depletion of organic matter and
fertility and disruption in cycles of water, organic carbon
and plant nutrient [3]. Use of excessive and unnecessary
tillage operations is often harmful to soil. Therefore,
currently there is a significant interest and emphasis on
the shift to the conservation and no-tillage methods for
the purpose of controlling erosion process [4].

Conventional tillage practices modify soil structure by
changing its physical properties such as soil bulk density,
soil penetration resistance and soil moisture content.
Annual disturbance and pulverizing caused by
conventional tillage produce a finer and loose soil
structure as compared to conservation and no-tillage
method which leaves the soil intact [5]. This difference
results in a change of number, shape, continuity and size
distribution of the pores network, which controls the
ability of soil to store and transmit air, water and
agricultural chemicals. This in turn controls erosion,
runoff and crop performance [6]. On the other hand,
conservation tillage methods often result in decreased
pore space [7], increased soil strength [8] and stable
aggregates [9]. The pore network in conservationally tilled
soil is usually more continuous because of earthworms,
root channels and vertical cracks [10]. Therefore,
conservation tillage may reduce disruption of continues
pores. Whereas, conventional tillage decreases soil
penetration resistance and soil bulk density [11]. This
also improves porosity and water holding capacity of the
soil. Continuity of pore network is also interrupted by
conventional tillage, which increases the tortuosity of
soil. This all leads to a favorable environment for crop
growth and nutrient use [6]. However, the results of
no-tillage are contradictory [4]. No-tillage methods in arid
regions of Iran had an adverse effect on crop yields [12];
while Chaudhary et al. [13] comparing conventional tillage
method to no-tillage method concluded that higher
moisture preservation and 13% more income was obtained
in case of no-tillage.

At this time, a wide range of tillage methods is being
used in Iran without evaluating their effects on soil
physical properties and crop yield. Therefore, the present
investigation was planned to determine the effect of
different tillage methods on soil physical properties and
crop yield of melon in the arid lands of Iran.

**MATERIALS AND METHODS**

A two year field experiment was conducted to
evaluate the effect of different tillage methods on soil
physical properties and crop yield of melon during 2006
and 2007 growing seasons at Research Site of Varamin
Agricultural Research Center, Iran. The site is located at
latitude of 35°-19’ N and longitude of 51°-39’ E and is
1000 m above mean sea level, in arid climate in the center
of Iran, where the summers are dry and hot while the
winters are cool. The soil of the experimental site was a
fine, mixed, thermic, Typic Haplacambids clay-loam soil.
Details of soil physical and chemical characteristics are
given in Table 1.

The experiments were laid out in a randomized
complete block design (RCBD) having three replications.
The size of each plot was 10.0 m long and 6.0 m wide.
A buffer zone of 5.0 m spacing was provided between
plots. There were two furrows in each plot. The furrows
had 10.0 m long, 75 cm wide and 50 cm depth and crop
was sown manually on the both sides of each furrow by
keeping row to row and plant to plant distance 3.0 m and
50 cm, respectively. The treatments were applied to the
same plots during the 2 year (2006-2007) on farm study.
Tillage treatments included one pass of moldboard plow
followed two passes of disk harrow as conventional
tillage (CT), two passes of disk harrow as reduced tillage
(RT), one pass of disk harrow as minimum tillage (MT)
and no-tillage (NT) as direct drilling method (Table 2).

In both growing season, one of the most commercial
variety of melon cv. Jalali (Souski) was planted at the rate
of 3 kg ha$^{-1}$ on 5th May. The seed moisture and
germination percentage were 15 and 95% respectively.
Recommended levels of N (300 kg ha$^{-1}$), P (200 kg ha$^{-1}$)
and K (100 kg ha$^{-1}$) were used as Urea, TSP and SOP,
respectively. Pest and weed controls were performed
according to general local practices and
recommendations. All other necessary operations except
those under study were kept normal and uniform for all
the treatments.

Standard procedures were adopted for recording the
data on various growth and yield parameters. Crop yield,
number of plants per hectare, number of fruits per plant,
fruit weight, fruit length, fruit diameter and total soluble
solids were determined by harvesting fruits of the two
middle rows of each plot. Other parameters, i.e. root length
and root dry matter, were determined from the 10 samples
taken randomly from each plot. Soil bulk density, soil
penetration resistance and soil moisture content was also determined at crop harvest. The soil bulk density on dry basis was determined for each treatment. For this test 10 undisturbed samples were taken from the plots by core sampler and dried 24 h at 105°C in an oven. Soil penetration resistance was measured by 10 insertions in each plot. A penetrometer (SP 1000) was used with 12.83 mm cone diameter and 30 degree angle based on ASAE standard S313.3 FEB04. Soil moisture content was also determined during cone index recording. The data collected were analyzed statistically using Completely Randomized Block Design (RCBD) as described by Steel and Torrie [14]. Duncan’s Multiple Range test at 5% probability was performed to compare the means of different treatments by using the computer software SPSS 12.0 (Version, 2003).

RESULTS

Crop Yield: Different tillage treatments significantly affected crop yield during both the years of study (Table 3). The highest crop yield of 27.2 t ha$^{-1}$ was obtained for the CT treatment and lowest (20.6 t ha$^{-1}$) for the NT treatment (Table 5).

Number of Plants per Hectare: A non-significant effect of different tillage treatments on number of plants per hectare was found during the study years (Table 3). However, the highest number of plants per hectare of 6360 was obtained for the CT treatment and lowest (5910) for the NT treatment (Table 5).

Number of Fruits per Plant: The effect of different tillage treatments on number of fruits per plant was also found non-significant during the years of study (Table 3). However, the highest number of fruits per plant of 1.9 was obtained for the CT treatment and lowest (1.2) for the RT treatment (Table 5).

Fruit Weight: Different tillage treatments significantly affected fruit weight during the study years (Table 3). The highest fruit weight 3.6 kg was obtained for the RT treatment and lowest (1.9 kg) for the NT treatment (Table 5).

Fruit Length: A significant effect of different tillage treatments on fruit length was also found during both the years of study (Table 3). The highest fruit length of 29.0 cm was obtained for the MT treatment and lowest (26.4 cm) for the NT treatment (Table 5).

Fruit Diameter: Different tillage treatments significantly affected fruit diameter during the years of study (Table 3). The highest fruit diameter of 17.2 cm was obtained for the MT treatment and lowest (14.1 cm) for the NT treatment (Table 5).

Total Soluble Solids: A significant effect of different tillage treatments on total soluble solids was also found during the study years (Table 3). The highest total soluble solids of 10.25% was obtained for the RT treatment and lowest (9.75%) for the MT treatment (Table 5).

**Root Length:** The effect of different tillage treatments on root length was found non-significant during the years of study (Table 3). However, the highest root length of 42.3 cm was obtained for the RT treatment and lowest (36.6 cm) for the NT treatment (Table 5).

**Root Dry Matter:** Different tillage treatments significantly affected root dry matter during both the years of study (Table 3). The highest root dry matter of 72.5% was obtained for the RT treatment and lowest (54.1%) for the NT treatment (Table 5).

**Soil Bulk Density:** Different tillage treatments significantly affected soil bulk density during both the years of study (Table 4). The highest soil bulk density of 1.52 g cm⁻³ was obtained for the NT treatment and lowest (1.41 g cm⁻³) for the CT treatment (Table 6).

**Soil Penetration Resistance:** A significant effect of different tillage treatments on soil penetration resistance was also found during the years of study (Table 4). The highest soil penetration resistance of 1250 kPa was obtained for the NT treatment and lowest (560 kPa) for the CT treatment (Table 6).

**Soil Moisture Content:** Different tillage treatments significantly affected soil moisture content during the study years (Table 4). The highest soil moisture content of 19.6% was obtained for the CT treatment and lowest (16.9%) for the NT treatment (Table 6).

**DISCUSSION**

In this study, effect of different tillage methods on soil physical properties and crop yield of melon was
investigated. The salient components of crop yield such as number of plants per hectare, number of fruits per plant, fruit weight, fruit length, fruit diameter, total soluble solids, root length and root dry matter were studied to analyze the effect of different tillage methods on growth and yield of melon. Also, data regarding soil bulk density, soil penetration resistance and soil moisture content were studied to analyze the effect of different tillage methods on soil physical properties. Results showed a significant response in the growth and yield parameters of melon and physical properties of soil.

The statistical results of the study indicated that tillage method significantly (P < 0.05) affected crop yield, fruit weight, fruit length, fruit diameter, total soluble solids and root dry matter, but there was no significant differences in other yield components such as number of plants per hectare, number of fruits per plant and root length among the different tillage treatments during the study years (Table 3). The maximum value of crop yield (27.2 t ha\(^{-1}\)), number of plants per hectare (6360) and number of fruits per plant (1.9) was obtained in case of CT treatment, while maximum value of fruit weight (3.6 kg), total soluble solids (10.25%), root length (42.3 cm) and root dry matter (72.5%) was observed in case of RT treatment. Also, maximum value of fruit length (29.0 cm) and fruit diameter (17.2 cm) was noted in case of MT treatment (Table 5). These results are in agreement with those of Khan et al. [6], who concluded that tillage practices produce a favorable environment for crop growth and nutrient use. These results are also in line with the results reported by Rashidi and Keshavarzpour [5] that annual disturbance and pulverizing caused by tillage practices produce a finer and loose soil structure which in turn affect the seedling emergence, plant population density and consequently crop yield. Conversely, the minimum value of crop yield (20.6 t ha\(^{-1}\)), number of plants per hectare (5910), fruit weight (1.9 kg), fruit length (26.4 cm), fruit diameter (14.1 cm), root length (36.6 cm) and root dry matter (54.1%) was obtained in case of NT treatment, while minimum value of number of fruits per plant (1.2) was observed in case of RT treatment. Also, minimum value of total soluble (9.75%) was noted in case of MT (Table 5). These results are in agreement with those of Hemmat and Taki [12], who concluded that no-tillage method in arid regions had an adverse effect on crop yields. These results are also in line with the results reported by Iqbal et al. [4] that no-tillage method can not compensate the adverse effect of fine texture, very low organic matter and an overall initial weak structure of the soil.

The statistical results of the study also indicated that tillage method significantly affected soil physical properties as they increased soil moisture content while decreased soil bulk density and soil penetration resistance among the different tillage treatments during both the years of study (Table 4). The soil of the CT treatment had consistently the highest moisture contents of 19.6% and lowest bulk density and penetration resistance of 1.41 g cm\(^{-1}\) and 560 kPa, respectively (Table 6). Alternatively, the soil of the NT treatment had the lowest moisture contents of 16.8% and the highest bulk density and penetration resistance of 1.52 g cm\(^{-1}\) and 1250 kPa, respectively (Table 6). The soils of the MT and NT treatments had almost the same soil bulk density and moisture content. However, the soil of NT treatment reflected high penetration resistance and showed about 14% more resistance than the resistance offered by the soil of the MT treatment (Table 6). A significantly greater soil moisture content of the CT treatment than other treatments was considered to be due to effect of primary and secondary tillage implements used which improved porosity and water holding capacity of the soil. These results are in agreement with those of Khan et al. [11], who reported that conventional tillage method increased soil tortuosity of the soil. Furthermore, significant lower soil bulk density and penetration resistance of the CT treatment was judged to be due to soil loosening effect of primary and secondary tillage implements used. These results are in line with the results reported by Khurshid et al. [1] that soil of the conventional tillage treatment had higher moisture content and lower bulk density and penetration resistance than other treatments. Greater soil penetration resistance of RT, MT and NT treatments may also be due to lower soil moisture contents. This is in line with the results reported by Ghuman and Lal [15] that penetration resistance decreased with increase in soil moisture content and vice versa.

**CONCLUSIONS**

Tillage method significantly affected crop yield of melon in the order of CT > RT > MT > NT. The highest amount of crop yield obtained in the CT method might be due to reduced soil penetration resistance and bulk density, increased soil moisture content, enhanced seed-soil contact and suppressing weed growth. Where in case of RT, MT and NT methods, the lower amounts of crop yield obtained may be due to significantly greater soil penetration resistance and bulk density and lower soil
moisture content which adversely affect seed emergence, root growth and plant population density. Therefore, moldboard plow followed by two passes of disk harrow was found to be more appropriate and profitable tillage method in improving soil physical properties and crop yield of melon.
